

A Case Report and Review of B-Lineage Acute Lymphoblastic Leukemias with Cannibalistic Lymphoblasts: A Unique Morphologic and Molecular Genetic Entity?

Abstract

Cannibalism is a type of “cell-in-cell” phenomenon commonly described in myeloid lineage malignancies. Although lymphocytes and their precursors are inherently non-phagocytic, there are sporadic case reports describing cannibalism by leukemic lymphoblasts. In the current manuscript, we report the case of a pediatric B-lineage acute lymphoblastic leukemia (B-ALL) patient showing cannibalistic lymphoblasts and have reviewed the clinical and laboratory characteristics of similar cases documented in literature. Our manuscript highlights that all reported B-ALL patients showing cannibalistic lymphoblasts had intra-cytoplasmic vacuolations, and all such treatment-naïve pediatric patients were *ETV6-RUNX1* fusion positive and had aberrant expression of myeloid lineage antigens.

Keywords: *Cannibalism, ETV6-RUNX1, pediatric, precursor B-lineage acute lymphoblastic leukemia*

Introduction

Cannibalism by leukemic blasts is well described in acute myeloid leukemias (AML). Although lymphocytes and their precursors are inherently nonphagocytic, nine cases of leukemic lymphoblasts exhibiting phagocytosis have been documented in literature.^[1-6] Through this manuscript, we report our pediatric B-lineage acute lymphoblastic leukemia (B-ALL) patient who had cannibalistic blasts at diagnosis and review the clinical and laboratory characteristics of similar cases reported in literature. Interestingly, all lymphoblastic leukemia patients with phagocytic lymphoblasts reported till date had unique morphologic features and all pediatric B-ALL patients (100%) of this genre were positive for *ETV6-RUNX1* fusion transcript.

Case Scenario

A 14-year-old Indian male presented with extreme fatigue and myalgia for 1 month. He was afebrile and had marked pallor and hepatomegaly. Hemogram revealed hemoglobin of 49 g/L, platelets of $127 \times 10^9/L$, and leukocytes of $15.8 \times 10^9/L$.

Myeloperoxidase (MPO)-negative blasts comprised 75% of circulating leukocytes and 96% of bone marrow nucleated cells. These blasts were 2–4 times the size of a mature lymphocyte, had opened up chromatin and scanty basophilic cytoplasm. Multiple cytoplasmic vacuolations were observed in 88% of the blasts, and 12% of blasts showed erythrophagocytosis or thrombophagocytosis or cannibalism [Figure 1]. Flow cytometric immunophenotyping (FCI) was consistent with B-ALL with aberrant myeloid lineage marker expression (CD19^{moderate}, CD10^{bright}, HLA-DR^{moderate}, CD34^{dim to moderate}, CD13^{moderate}, CD33^{moderate}, CD36^{negative to dim}, cytoplasmic CD79a^{moderate}, cytoplasmic CD22^{moderate}, cytoplasmic MPO^{negative}, and cytoplasmic CD3^{negative}). Qualitative reverse-transcriptase-polymerase chain reaction revealed *ETV6-RUNX1* fusion transcript positivity. There was no leukemic central nervous system infiltration at diagnosis.

After the confirmation of diagnosis, the patient's family was counseled about the disease and treatment options. Due to financial constraints, the family wished to continue therapy at the local place. Hence, he was started on 6-week induction with low-dose chemotherapy protocol comprising

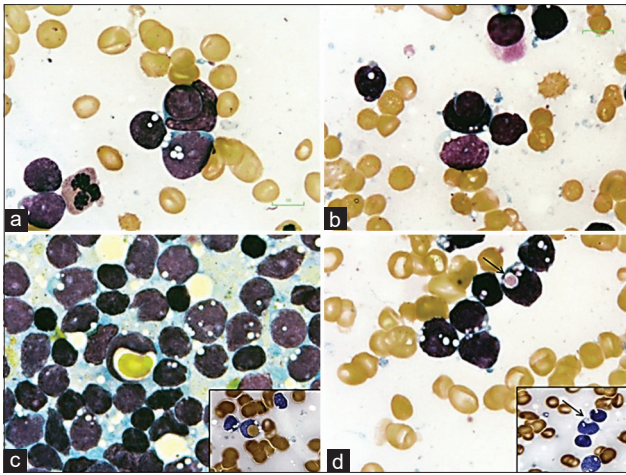

Figure 1: Note the presence of prominent vacuolations in the blasts. (a and b) Blasts showing cannibalism; (c) blast with erythrophagocytosis. Inset shows myeloperoxidase-positive erythrocyte engulfed by a blast; (d) thrombophagocytosis by blast. Inset shows myeloperoxidase-negative platelet engulfed by a blast. All slides are May–Grünwald–Giemsa stained, and the insets are cytochemical-myeloperoxidase stained ($\times 100$)

weekly vincristine 1.5 mg/m² and daily prednisolone 60 mg/m² for 4 weeks followed by taper. The patient never followed up after he was discharged after receiving week 1 induction. As per telephonic information, the patient was shifted to indigenous treatment and succumbed to his illness after 7 months of diagnosis.

Discussion

Cellular cannibalism is a type of “cell-into-cell” phenomenon, wherein a viable cell is irreversibly engulfed by a nonprofessional phagocyte.^[7] A cannibalistic cell can engulf a cell of its own lineage (homotypic cannibalism) or of different lineage (xeno-cannibalism).^[8] Cannibalism is different from phagocytosis, wherein the latter involves a professional phagocytic cell (histiocyte/macrophage) engulfing a nonviable cell.^[7,8] Though phagocytosis can be seen in both benign and malignant pathologies, cannibalism is pathognomonic of advanced malignancies.^[8]

Among acute leukemias, xeno-cannibalism in the form of erythrophagocytosis by neoplastic blasts has been commonly documented in cases of AML with monocyte lineage differentiation, AML with maturation, AML without maturation, acute megakaryoblastic leukemia, mixed phenotype acute leukemia, and acute undifferentiated leukemia.^[1,9] In AMLs, xeno-cannibalism has been associated with t(8;16)(p11;p13), t(16;21)(p11;q22), t(10;17)(p13;p12), inv(8)(p11q13), t(16;21)(p11;q22), t(3;8;7)(q27;p11;q12), del(20)(q11), and t(8;21)(q22;q22).^[1]

Although conventional lymphocytes and their precursors are inherently nonphagocytic, cannibalism by leukemic lymphoblasts has been reported in nine patients till date.^[1-6] The first documentation of xeno-cannibalism in lymphoblasts was by Foadi *et al.* in 1978, where both erythrophagocytosis and thrombophagocytosis were observed in four relapsed

ALL patients, but the lineage commitment of these lymphoblasts was not disclosed.^[4] In 1984, Colon-Otero *et al.* reported the first case of erythrophagocytosis by lymphoblasts in a newly diagnosed B-ALL patient.^[2] Till date, to our knowledge, cannibalism has been documented in only five treatment-naïve B-ALL patients (one adult and four pediatric) and ours is the sixth case in this genre.^[1-3,5] The clinical and laboratory characteristics of these six patients are compiled in Table 1.

Interestingly, all the five pediatric B-ALL patients with cannibalistic lymphoblast were positive for *ETV6-RUNX1* fusion (100%). A lone adult B-ALL patient diagnosed with cannibalistic B-lymphoblasts had del(20)(q11), a cytogenetic aberrancy that has also been reported in AML and MDS patients with cannibalism.^[10] None of these patients had concurrent hemophagocytic histiocytosis in the bone marrow. Interestingly, 67% of these patients had near-normal platelet counts, and lymphoblasts of all these patients (100%) showed intracytoplasmic vacuolations. These intracytoplasmic vacuolations were also observed in the relapsed ALL patients documented by Foadi *et al.*^[4] Comprehensive FCI data available in four patients revealed the aberrant expression of myeloid lineage antigens (CD13 and/or CD33) in all (100%).

As lymphocytes and their precursors are inherently nonphagocytic, acquisition of phagocytic phenotype in leukemic lymphoid blasts is unexpected. In relapsed lymphoblastic leukemia patients presenting with cannibalism, Foadi *et al.* have hypothesized that prolonged exposure to chemotherapy might have triggered a new clone of leukemic lymphoblasts bestowed with phagocytic capability. However, chemotherapy exposure is less likely to be a risk factor as 60% (six of ten cases described) of B-ALL patients with cannibalistic lymphoblasts were treatment naïve.

Colon-Otero *et al.* have proposed that acquisition of phagocytic property in treatment-naïve lymphoblasts might be due to tumor cell dedifferentiation causing aberrant expression of complement receptors (CR1 and CR3), receptors for Fc region of IgG and gp150 (receptor for fimbriae) on the blasts.^[2] However, prospective evidences demonstrating expression of these above-mentioned receptors in cannibalistic B-lymphoblasts are not available. Hence, the pathogenesis of cannibalism in leukemic B-lymphoblast is still an enigma.

Regarding the prognostic relevance of cannibalistic B-lymphoblasts, an elderly treatment-naïve B-ALL patient with del(20)(q11) and all the four relapsed B-ALL patients presenting with cannibalistic lymphoblasts had dismal outcomes marred with either disease relapse or mortality.^[2,4] However, all the newly diagnosed pediatric B-ALL patients, including those diagnosed above 10 years of age, were *ETV6-RUNX1* fusion positive and had optimistic survival without disease relapse or mortality.

Table 1: Clinical and laboratory characteristics of B-lineage acute lymphoblastic leukemia patients with cannibalistic blasts

Conclusion

Due to the limited number of cases documented in literature, it is still premature to arrive at any concrete conclusions regarding the prognostic and clinical relevance of cannibalistic B-lymphoblasts. However, our manuscript highlights that all reported B-ALL patients showing cannibalistic lymphoblasts had intracytoplasmic vacuolations (100%), and all such treatment-naïve pediatric patients were *ETV6-RUNX1* fusion positive (100%) with aberrant expression of myeloid lineage antigens.
